

MOVIE DATABASE - EF Console

Objective: Build a Movie database and an EF/Console app that uses it. You will use this database in future labs.

Build Specifications:

1. Use Database First and create a movie database. The database should contain a table named "Movies" with the following Columns:
 - int Id - Primary Key
 - nvarchar(50) Title
 - nvarchar(20) Genre
 - double Runtime
2. Create a static function in your program class that populates your table with 10 to 15 movies. Call this function from your main; run it; then remove the call from your main so it doesn't run again.
3. Create two methods:

Search by Genre: This method will return a list of Movie instances that match the genre.

Search by Title: This method will return a list of Movie instances that match the title.

Hint: Use the .ToList() method on the table to get it into list format.

4. Write a console application that displays a menu and asks the user whether they wish to search by genre or title. Then allow the user to enter either genre or title respectively. Call the appropriate method to retrieve the movies. Print out the movie information to the console.
